November 6, 2003

Abstract

XORP Resource Locators are the XORP projects preferred means for inter-process communication. A description of the XRL's can be found in [1]. This document describes an important aspect of the XRL world: the specification of XRL Interfaces and Targets. Following these specifications this document then describes tools that generate XRL marshalling and unmarshalling routines and assist in common case XRL handling.

1 Introduction

Up until the interface specification language and tools described here, only a low-level API was available for dispatching and handling XRL requests. The primary goal of the interface specification language and tools is to make the common case XRL code less cumbersome and more consistent. In addition, the interface specification language embeds versioning information which can be used to maintain backwards compatibility as interface develop and minimize conflicts following revisions.

2 Terminology

We define an *XRL Target* as something that XRL requests can be directed to in order to be executed. Multiple XRL targets can exist within a single process, though there will typically be one target per process. Each XRL Target has an associated name and a set of IPC mechanisms that it supports. At start-up each target registers its name and IPC mechanisms with the Finder, so other processes are able to direct requests to it.

We define an *XRL Interface* to be a set of related methods that an XRL Target would implement. Each XRL Interface is uniquely identified by a name and version number. An XRL Target will nearly always implement multiple interfaces and potentially multiple versions of particular interface. For instance, every XRL Target could implement a process information interface that would return information about the process hosting the target. Each XRL Target will implement interfaces specific to their field of operation: a routing process would implement the "routing process interface" so that the RIB process can make identity-agnostic XRL calls for tasks like redistributing a route to another routing protocol.

We define an *XRL Interface Client* to be a process that accesses a particular XRL Interface.

These definitions are illustrated in figure 1.

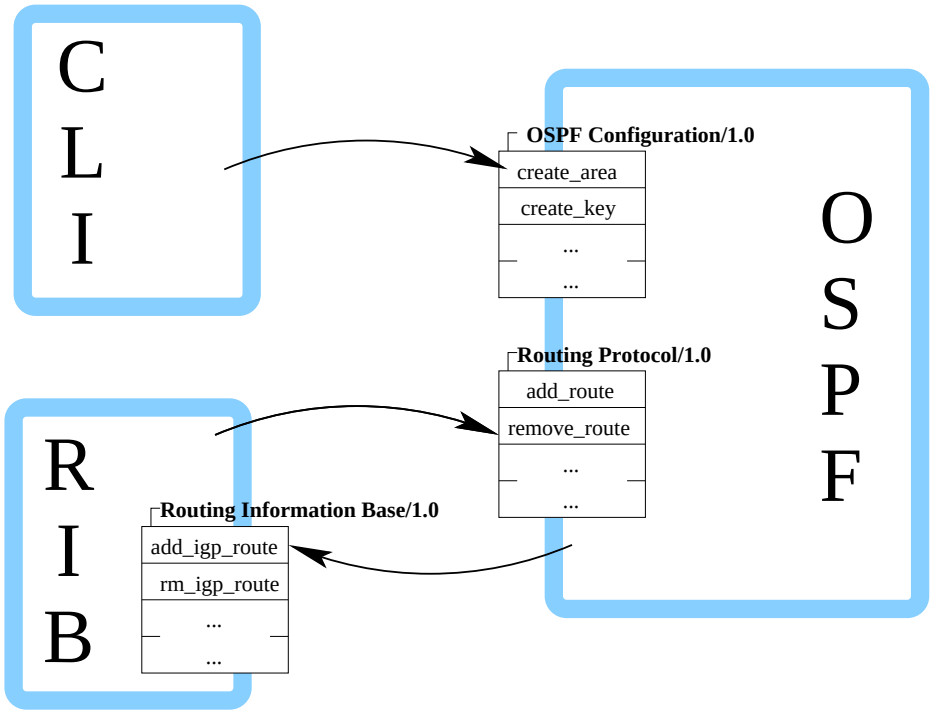

Figure 1: Example XRL Targets and clients: OSPF, RIB, and CLI. OSPF and RIB processes are XRL targets. OSPF supports XRL interfaces “OSPF Configuration/1.0” and “Routing Protocol/1.0”: the RIB is a client of the former interface and the CLI a client of the latter.

3 Interface and Target Specifications

3.1 Interface Specifications

An interface is declared using the **interface** keyword and a set of XRL methods associated with it.

interface <*interface name*>/<*interface version*> { . . . *xrl method list* . . . }

Each item in the XRL Method list consists of a method name, its dispatch arguments, and return arguments specified in the default XRL text form. An example of this is shown in listing 1.

Listing 1: Example Xrl Interface Specification

```
/* $XORP: xorp/xrl/interfaces/test.xif,v 1.1.1.1 2002/12/11 23:56:18 hodson Exp $ */

/*
 * This is a test file with XRL interface.
 */

interface test/1.0 {
        /**
         * Print hello world
         */
        print_hello_world

        /**
         * Print "hello world" and a user supplied greeting.
         * @param msg greeting to be printed.
         */

         print_hello_world_and_message ? msg:txt

         /**
          * Count number of greetings available
          */
         get_greeting_count -> num_msgs:i32

         /**
          * Get greeting
          *
          * @param greeting_num index of greeting
          *
          * @param greeting text of greeting.
          */
         get_greeting ? greeting_num:i32 -> greeting:txt

         /**
          * Something that always fails.
          */
         shoot_foot
}
```

Whitespace can be used to separate XRL Atoms in the description and backslashes can be used to continue XRL descriptions across multiple lines. [NB This usage of spacing is not currently supported elsewhere in the project - to be fixed.]

C-style comments are valid anywhere with interface specification files and kdoc comments can be used to describe the XRL, its arguments, and return values. Each kdoc comment is associated with the next XRL found in a specification file. All kdoc tags are valid with the exception of **@return** which is used by kdoc to describe C/C++ single return values (for XRL's return values should be document with **@param** since they are named and groups of values can be returned).

By convention, XRL Interfaces are specified in `.xif` files and these are located in the `xorp/xrl/interfaces` directory.

3.2 Target Specifications

XRL Targets are declared in *.tgt* files using:

target $<$ *target name* $>$ **implements** <*interface*> [, <*interface*> ...]

Target specification files use the standard C include primitive to include the appropriate interface specifications. An example is shown in listing 2 and further examples can be found in the `xorp/xrl/targets` directory.

Listing 2: Example XRL Target specification.

```
/* $XORP: xorp/xrl/targets/test.tgt,v 1.1.1.1 2002/12/11 23:56:19 hodson Exp $ */

#include "common.xif"
#include "test.xif"

target test implements common/0.1, test/1.0
```

4 Tools

We use XRL Interface and XRL Target specifications to generate code that takes some of the tedium out of writing XRL related code. We have written two scripts: clnt-gen and tgt-gen that generate C++ header files and libraries and also produce a list of XRL's for each XRL Target.

4.1 clnt-gen : XRL Interface Client Generator

clnt-gen parses Xrl Interface specifications and generates a header and related library source file to simplify invoking the XRL's of that interface. Each XRL Interface specification generates an XRL Interface Client C++ class. The generated C++ class has a send method for each XRL in the XRL interface specification and takes care of argument marshalling when the XRL is dispatched and when it returns.

A fragment of generated code is shown in listing 3. This code is generated from the Xrl Interface presented in listing 1. The Xrl Interface Client C++ has a constructor that takes a XrlRouter object that holds the necessary state to correlate the XRLs being called with the return values. Each XRL specified in the XRL Interface has a send method. The send method takes the name of Xrl Target, the native C++/XORP arguments to be passed as XRL arguments, and a callback argument to be invoked when the XRL returns.

The type of the XRL callback is determined by the return type specification of the XRL. Since the syntax for the callback is awkward, a typedef is used in the class method. The relevant typedef appears immediately before each send method. When called, the first callback argument of the callback is an `XrlError` object. If the value is `XrlError::OKAY()` then return values from the XRL will be pointed to by the following arguments (*e.g.*, const string* for string argument). Otherwise, the return value pointers will be `NULL` since there is no data available for return values when errors occur.

The interested reader should refer to the directory `xorp/xrl/tests/` for examples using the client interface.

Listing 3: Fragment of a C++ XRL Client.

```
class XrlTestV1p0Client {
public:
    XrlTestV1p0Client(XrlRouter* r) : _router(r) {}
    virtual ~XrlTestV1p0Client() {}

    /* ... */

    typedef XorpCallback2<void, const XrlError&, const string*>::RefPtr CB3;
    /**
     *  Send Xrl intended to:
     *
     *  Get greeting
     *
     *  @param tgt_name Xrl Target name
     *
     *  @param greeting_num index of greeting
     */
    void send_get_greeting(
        const char*     target_name,
        const int32_t&  greeting_num,
        const CB3&      cb
    );

    /* ... */
};
```

4.2 tgt-gen : XRL Target Generator

tgt-gen takes an XRL target specification and generates list of XRL's supported by the target and a class to be sub-classed that takes care of argument marshalling and unmarshalling and sanity checks.

The XRL's for the `test/1.0` that was target presented in listing 2 are shown in listing 4. Notice that the name of each XRL has the interface and version that it belongs to prepended. This is the mechanism used to support the concept of interfaces and to support versioning.

As far as the generated base class is concerned, it implements a set of pure-virtual Xrl handler methods each of which is associated with handling a specific XRL. The implementor derives from the base class, implementing the pure-virtual methods. When an XRL request is received, it will be forwarded to the derived class's implementation handler method. The base class takes care of marshalling and unmarshalling Xrl arguments and error handling.

The design to derive a class to implement the handler functions was, in part, taken to encourage (force) people to implement handlers for all the XRL's specified for the XRL Target. In addition, implementors can add whatever state they require in dispatching XRL's to the handler class, ie pointers or references to data structures.

An example of a generated target header is shown in listing 5. Notice that the input Xrl arguments are const reference arguments to the C++ method, and the Xrl return arguments are just reference arguments.

Listing 4: Example XRL list generated from Xrl Target specification.
