

# Package ‘veloviz’

December 12, 2025

**Title** VeloViz: RNA-velocity informed 2D embeddings for visualizing cell state trajectories

**Version** 1.16.0

**Description** VeloViz uses each cell’s current observed and predicted future transcriptional states inferred from RNA velocity analysis to build a nearest neighbor graph between cells in the population. Edges are then pruned based on a cosine correlation threshold and/or a distance threshold and the resulting graph is visualized using a force-directed graph layout algorithm. VeloViz can help ensure that relationships between cell states are reflected in the 2D embedding, allowing for more reliable representation of underlying cellular trajectories.

**biocViews** Transcriptomics, Visualization, GeneExpression, Sequencing, RNASeq, DimensionReduction

**License** GPL-3

**Encoding** UTF-8

**LazyData** false

**Roxygen** list(markdown = TRUE)

**RoxygenNote** 7.1.1

**Imports** Rcpp, Matrix, igraph, mgcv, RSpectra, grDevices, graphics, stats

asNNGraph

*Function to produce idx and dist representation of a VeloViz graph*

---

### Description

Function to produce idx and dist representation of a VeloViz graph

### Usage

```
asNNGraph(vig)
```

### Arguments

vig                      output of buildVeloviz

### Value

idx numVertices x numNeighbors matrix, where each row i contains indices of vertex i's neighbors  
 dist numVertices x numNeighbors matrix, where each row i contains distances from vertex i to its neighbors

### Examples

```
data(vel)
curr <- vel$current
proj <- vel$projected

vv <- buildVeloviz(curr = curr, proj = proj, normalize.depth = TRUE,
  use.ods.genes = FALSE, alpha = 0.05, pca = TRUE, nPCs = 3, center = TRUE,
  scale = TRUE, k = 10, similarity.threshold = -1, distance.weight = 1,
  distance.threshold = 1, weighted = TRUE, verbose = FALSE)

asNNGraph(vv)
```

---

|              |                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------|
| buildVeloviz | <i>Creates VeloViz graph and FDG layout from PC scores of current and projected transcriptional states.</i> |
|--------------|-------------------------------------------------------------------------------------------------------------|

---

## Description

Creates VeloViz graph and FDG layout from PC scores of current and projected transcriptional states.

## Usage

```
buildVeloviz(
  curr,
  proj,
  normalize.depth = TRUE,
  depth = 1e+06,
  use.ods.genes = TRUE,
  max.ods.genes = 2000,
  alpha = 0.05,
  pca = TRUE,
  center = TRUE,
  scale = TRUE,
  nPCs = 10,
  k = 10,
  similarity.threshold = 0,
  distance.weight = 1,
  distance.threshold = 1,
  weighted = TRUE,
  remove.unconnected = TRUE,
  verbose = FALSE,
  details = FALSE
)
```

## Arguments

|                 |                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------|
| curr            | Genes (rows) x cells (columns) matrix of observed current transcriptional state                                       |
| proj            | Genes (rows) x cells (columns) matrix of predicted future transcriptional state                                       |
| normalize.depth | logical to normalize raw counts to counts per million, default = TRUE                                                 |
| depth           | Depth scaling, default = 1e6 for counts per million (CPM)                                                             |
| use.ods.genes   | Use only overdispersed genes to create VeloViz graph, default = TRUE                                                  |
| max.ods.genes   | number of most highly expressed overdispersed genes to use to create VeloViz graph, default = 2000                    |
| alpha           | Significance threshold for overdispersed genes, default = 0.05                                                        |
| pca             | logical to use PC scores to create VeloViz graph, default = TRUE. FALSE = use gene expression to create VeloViz graph |
| center          | logical to mean center gene expression before PCA, default = TRUE                                                     |
| scale           | logical to scale gene expression variance before PCA, default = TRUE                                                  |

|                      |                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| nPCs                 | number of principal components to use to create VeloViz graph, default = 10                                                            |
| k                    | Number of nearest neighbors to assign each cell                                                                                        |
| similarity.threshold | similarity threshold below which to remove edges, default = -1 i.e. no edges removed                                                   |
| distance.weight      | Weight of distance component of composite distance, default = 1                                                                        |
| distance.threshold   | quantile threshold for distance component above which to remove edges, default = 1 i.e. no edges removed                               |
| weighted             | logical indicating whether to compute VeloViz edges based on composite distance, default = TRUE. FALSE = all edges are of equal weight |
| remove.unconnected   | logical indicating whether to remove cells with no edges in the VeloViz graph from the output embedding, default = TRUE (removed)      |
| verbose              | logical for verbosity setting, default = FALSE                                                                                         |
| details              | logical to return detailed data frame or names of genes, default = FALSE                                                               |

**Value**

graph igraph object of VeloViz graph

fdg\_coords cells (rows) x 2 coordinates of force-directed layout of VeloViz graph

projectedNeighbors output of projectedNeighbors

**See Also**

[projectedNeighbors](#)

**Examples**

```
data(vel)
curr <- vel$current
proj <- vel$projected

buildVeloviz(curr = curr, proj = proj, normalize.depth = TRUE,
use.ods.genes = TRUE, alpha = 0.05, pca = TRUE, nPCs = 20, center = TRUE,
scale = TRUE, k = 5, similarity.threshold = 0.25, distance.weight = 1,
distance.threshold = 0.5, weighted = TRUE, verbose = FALSE)
```

---

graphViz

---

Visualize as velocity informed force directed graph

---

**Description**

Visualize as velocity informed force directed graph

**Usage**

```

graphViz(
  observed,
  projected,
  k,
  distance_metric = "L2",
  similarity_metric = "cosine",
  distance_weight = 1,
  distance_threshold = 1,
  similarity_threshold = -1,
  weighted = TRUE,
  remove_unconnected = TRUE,
  return_graph = FALSE,
  plot = TRUE,
  cell.colors = NA,
  title = NA
)

```

**Arguments**

|                      |                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| observed             | PCs (rows) x cells (columns) matrix of observed transcriptional state projected into PC space                                                                                          |
| projected            | PCs (rows) x cells (columns) matrix of projected transcriptional states. Cell should be in same order as in observed                                                                   |
| k                    | Number of nearest neighbors to assign each cell                                                                                                                                        |
| distance_metric      | Method to compute distance component of composite distance. "L1" or "L2", default = "L2"                                                                                               |
| similarity_metric    | Method to compute similarity between velocity and cell transition matrices. "cosine" or "pearson", default = "cosine"                                                                  |
| distance_weight      | Weight of distance component of composite distance, default = 1                                                                                                                        |
| distance_threshold   | quantile threshold for distance component above which to remove edges, default = 1 i.e. no edges removed                                                                               |
| similarity_threshold | similarity threshold below which to remove edges, default = -1 i.e. no edges removed                                                                                                   |
| weighted             | if TRUE, assigns edge weights based on composite distance, if FALSE assigns equal weights to all edges, default = TRUE                                                                 |
| remove_unconnected   | if TRUE, does not plot cells with no edges, default = TRUE                                                                                                                             |
| return_graph         | if TRUE, returns igraph object graph, force-directed layout coordinates fdg_coords, and projected_neighbors object detailing composite distance values and components, default = FALSE |
| plot                 | if TRUE, plots graph and force-directed layout                                                                                                                                         |
| cell.colors          | cell.colors to use for plotting                                                                                                                                                        |
| title                | title to use for plot                                                                                                                                                                  |

**Value**

graph igraph object of VeloViz graph  
 fdg\_coords cells (rows) x 2 coordinates of force-directed layout of VeloViz graph  
 projectedNeighbors output of projectedNeighbors

**See Also**

[projectedNeighbors](#)

**Examples**

```
data(vel)
curr = vel$current
proj = vel$projected

m <- log10(curr+1)
pca <- RSpectra::svds(A = Matrix::t(m), k=3,
  opts = list(center = FALSE, scale = FALSE, maxitr = 2000, tol = 1e-10))
pca.curr <- Matrix::t(m) %*% pca$v[,1:3]

m <- log10(proj+1)
pca.proj <- Matrix::t(m) %*% pca$v[,1:3]

graphViz(t(pca.curr), t(pca.proj), k=10,
  cell.colors=NA, similarity_threshold=-1, distance_weight = 1,
  distance_threshold = 1, weighted = TRUE, remove_unconnected = TRUE,
  plot = FALSE, return_graph = TRUE)
```

---

|                |                                 |
|----------------|---------------------------------|
| normalizeDepth | <i>Normalizes counts to CPM</i> |
|----------------|---------------------------------|

---

**Description**

Normalizes raw counts to counts per million

**Usage**

```
normalizeDepth(counts, depthScale = 1e+06, verbose = TRUE)
```

**Arguments**

|            |                                                                                         |
|------------|-----------------------------------------------------------------------------------------|
| counts     | Read count matrix. The rows correspond to genes, columns correspond to individual cells |
| depthScale | Depth scaling. Using a million for CPM (default: 1e6)                                   |
| verbose    | Boolean for verbosity setting (default: TRUE)                                           |

**Value**

a normalized matrix

**Examples**

```
data(vel)
curr <- vel$current

normalizeDepth(curr)
```

---

|                   |                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| normalizeVariance | <i>Identify overdispersed genes by normalizing counts per million (CPM) gene expression variance relative to transcriptome-wide expectations (Modified from SCDE/PAGODA2 code)</i> |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

---

**Description**

Normalizes gene expression magnitudes to with respect to its ratio to the transcriptome-wide expectation as determined by local regression on expression magnitude

**Usage**

```
normalizeVariance(
  cpm,
  gam.k = 5,
  alpha = 0.05,
  max.adjusted.variance = 1000,
  min.adjusted.variance = 0.001,
  verbose = TRUE,
  plot = FALSE,
  details = FALSE
)
```

**Arguments**

|                       |                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|
| cpm                   | Counts per million (CPM) matrix. Rows are genes, columns are cells.                                             |
| gam.k                 | Generalized additive model parameter; the dimension of the basis used to represent the smooth term (default: 5) |
| alpha                 | Significance threshold for overdispersed genes (default: 0.05)                                                  |
| max.adjusted.variance | Ceiling on maximum variance after normalization to prevent infinities (default: 1e3)                            |
| min.adjusted.variance | Floor on minimum variance after normalization (default: 1e-3)                                                   |
| verbose               | Boolean for verbosity setting (default: TRUE)                                                                   |
| plot                  | Boolean to plot mean variance plots before and after correction                                                 |
| details               | Boolean to return detailed data frame or names of genes (default: FALSE)                                        |

**Value**

A list with two items: (1) an adjusted CPM matrix with the same dimensions as the input and (2) a dataframe with the summary statistics for each gene.

**Examples**

```
data(vel)
curr <- vel$current

normalizeDepth(curr)
```

---

|----------|--------------------------------|
| pancreas | <i>Pancreas scRNA-seq data</i> |
|----------|--------------------------------|

---

**Description**

Pancreatic endocrinogenesis scRNA-seq from Bastidas-Ponce et. al., Development 2019 accessed via scVelo package and subsampled to 739 cells.

**Usage**

```
pancreas
```

**Format**

list of 4 objects:

**spliced** matrix, 7192 genes x 739 cells of spliced counts

**unspliced** matrix, 7192 genes x 739 cells of unspliced counts

**pcs** matrix, 739 x 50 cell scores in 50 PCs

**clusters** factor of cell type annotations from scVelo

**Description**

Plot 2D embedding From scde/pagoda2/MUDAN

**Usage**

```
plotEmbedding(
  emb,
  groups = NULL,
  colors = NULL,
  cex = 0.6,
  alpha = 0.4,
  gradientPalette = NULL,
  zlim = NULL,
```

```

s = 1,
v = 0.8,
min.group.size = 1,
show.legend = FALSE,
mark.clusters = FALSE,
mark.cluster.cex = 2,
shuffle.colors = FALSE,
legend.x = "topright",
gradient.range.quantile = 0.95,
verbose = TRUE,
unclassified.cell.color = "gray70",
group.level.colors = NULL,
...
)

```

### Arguments

|                         |                                                                         |
|-------------------------|-------------------------------------------------------------------------|
| emb                     | dataframe with x and y coordinates                                      |
| groups                  | factor annotations for rows on emb for visualizing cluster annotations  |
| colors                  | color or numeric values for rows on emb for visualizing gene expression |
| cex                     | point size                                                              |
| alpha                   | point opacity                                                           |
| gradientPalette         | palette for colors if numeric values provided                           |
| zlim                    | range for colors                                                        |
| s                       | saturation of rainbow for group colors                                  |
| v                       | value of rainbow for group colors                                       |
| min.group.size          | minimum size of group in order for group to be colored                  |
| show.legend             | whether to show legend                                                  |
| mark.clusters           | whether to mark clusters with name of cluster                           |
| mark.cluster.cex        | cluster marker point size                                               |
| shuffle.colors          | whether to shuffle group colors                                         |
| legend.x                | legend position ie. 'topright', 'topleft', 'bottomleft', 'bottomright'  |
| gradient.range.quantile | quantile for mapping colors to gradient palette                         |
| verbose                 | verbosity                                                               |
| unclassified.cell.color | cells not included in groups will be labeled in this color              |
| group.level.colors      | set group level colors. Default uses rainbow.                           |
| ...                     | Additional parameters to pass to <code>BASE::plot</code>                |

### Value

embedding plot

**Examples**

```

data(vel)
curr <- vel$current
proj <- vel$projected

vv <- buildVeloviz(curr = curr, proj = proj, normalize.depth = TRUE,
  use.ods.genes = TRUE, alpha = 0.05, pca = TRUE, nPCs = 20, center = TRUE,
  scale = TRUE, k = 5, similarity.threshold = 0.25, distance.weight = 1,
  distance.threshold = 0.5, weighted = TRUE, verbose = FALSE)

plotEmbedding(vv$fdg_coords)

```

---

|             |                      |
|-------------|----------------------|
| plotVeloviz | <i>Plot function</i> |
|-------------|----------------------|

---

**Description**

Plot function

**Usage**

```

plotVeloviz(
  vig,
  layout.method = igraph::layout_with_fr,
  clusters = NA,
  cluster.method = igraph::cluster_louvain,
  col = NA,
  alpha = 0.05,
  verbose = TRUE
)

```

**Arguments**

|                |                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------|
| vig            | output of buildVeloviz                                                                              |
| layout.method  | igraph method to use for generating 2D graph representation, default = igraph::layout_with_fr       |
| clusters       | cluster annotations for cells in data                                                               |
| cluster.method | igraph method to use for clustering if clusters are not provided, default = igraph::cluster_louvain |
| col            | colors to use for plotting                                                                          |
| alpha          | transparency for plotting graph nodes                                                               |
| verbose        | logical for verbosity setting, default = FALSE                                                      |

**Value**

cells (rows) x 2 coordinates of force-directed layout of VeloViz graph

**Examples**

```

data(vel)
curr <- vel$current
proj <- vel$projected

vv <- buildVeloviz(curr = curr, proj = proj, normalize.depth = TRUE,
  use.ods.genes = TRUE, alpha = 0.05, pca = TRUE, nPCs = 20, center = TRUE,
  scale = TRUE, k = 5, similarity.threshold = 0.25, distance.weight = 1,
  distance.threshold = 0.5, weighted = TRUE, verbose = FALSE)

plotVeloviz(vv)

```

---

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| projectedNeighbors | <i>Computes composite distances between all cell pairs and returns k-nearest neighbors and edge weights needed to build VeloViz graph.</i> |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|

---

**Description**

Computes composite distances between all cell pairs and returns k-nearest neighbors and edge weights needed to build VeloViz graph.

**Usage**

```

projectedNeighbors(
  observed,
  projected,
  k,
  distance_metric = "L2",
  similarity_metric = "cosine",
  distance_weight = 1,
  distance_threshold = 1,
  similarity_threshold = -1
)

```

**Arguments**

|                   |                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| observed          | PCs (rows) x cells (columns) matrix of observed transcriptional state projected into PC space                         |
| projected         | PCs (rows) x cells (columns) matrix of projected transcriptional states. Cells should be in same order as in observed |
| k                 | Number of nearest neighbors to assign each cell                                                                       |
| distance_metric   | Method to compute distance component of composite distance. "L1" or "L2", default = "L2"                              |
| similarity_metric | Method to compute similarity between velocity and cell transition matrices. "cosine" or "pearson", default = "cosine" |
| distance_weight   | Weight of distance component of composite distance, default = 1                                                       |

distance\_threshold  
                   quantile threshold for distance component above which to remove edges, default = 1 i.e. no edges removed

similarity\_threshold  
                   similarity threshold below which to remove edges, default = -1 i.e. no edges removed

### Value

kNNs cells (rows) x k (columns) matrix of indices of each cell's nearest neighbors computed based on composite distance. Edges removed based on distance or similarity threshold will be NA.

edge\_weights cells (rows) x k (columns) matrix of edge weights computed based on composite distance. Edges removed based on distance or similarity threshold will be NA.

all\_dists cells x cells matrix of all pairwise composite distances

dist\_comp components of composite distance: invDist distance component, negSim similarity component

### Examples

```
data(vel)
curr <- vel$current
proj <- vel$projected

projectedNeighbors(curr, proj, 10)
```

---

|                  |                                                                                    |
|------------------|------------------------------------------------------------------------------------|
| reduceDimensions | <i>Reduce dimension using Principal Components Analysis via svds from RSpectra</i> |
|------------------|------------------------------------------------------------------------------------|

---

### Description

Reduce dimension using Principal Components Analysis via svds from RSpectra

### Usage

```
reduceDimensions(
  matnorm,
  center = TRUE,
  scale = TRUE,
  max.ods.genes = 2000,
  nPCs = 50,
  verbose = TRUE,
  plot = FALSE,
  details = FALSE
)
```

**Arguments**

|               |                                                                                |
|---------------|--------------------------------------------------------------------------------|
| matnorm       | matrix on which to perform PCA                                                 |
| center        | logical to mean center gene expression before PCA, default = TRUE              |
| scale         | logical to scale gene expression variance before PCA, default = TRUE           |
| max.ods.genes | number of most highly expressed overdispersed genes to include, default = 2000 |
| nPCs          | number of principal components to reduce to return, default = 50               |
| verbose       | logical for verbosity setting, default = TRUE                                  |
| plot          | plot singular values vs number of components                                   |
| details       | logical to return pca object, default = FALSE                                  |

**Value**

matrix of cell scores in nPCs components

**Examples**

```
data(vel)
curr <- vel$current

curr.norm <- normalizeDepth(curr)
curr.norm <- log10(curr.norm+1)
reduceDimensions(curr.norm, nPCs=3)
```

---

|     |                                |
|-----|--------------------------------|
| vel | <i>MERFISH velocity subset</i> |
|-----|--------------------------------|

---

**Description**

output of velocity.R::gene.relative.velocity.estimates for 40 cell subset of MERFISH data. Used to run examples

**Usage**

```
vel
```

**Format**

list of 1:

**vel** velocity output containing current observed ("current") and predicted future ("projected") estimates
